ATILIM UNIVERSITY

ANKARA

2020-2021 FALL SEMESTER CHE 105 GENERAL CHEMISTRY LABORATORY RULES

1. Laboratory lectures of CHE 105 course will be held on ZOOM platform.
2. You should have a **lab manual** and **calculator** during laboratory lectures.
3. Read the lab experiments before attending to laboratory lessons.
4. You will take a **quiz** at the beginning of the experiment.
5. **Cheating will lead to a zero point for quizzes and lab reports. If it is repeated second time, you will fail from the course and get a disciplinary warning.**
6. You have to fill your data sheet after experiment video and submit your data sheet with report sheet.
7. **If you miss more than one of the experiments without an excuse, then you will fail from the lab and also fail from CHE 105 course.**
8. In order to pass the lab, you have to get overall **50** points over 100 points **(Quizzes: 25%, Data Sheet: 25%, Lab Reports: 50%).**
9. To be able to take a makeup from any laboratory experiments, you should e-mail an **approved medical report** to the assistants.
10. If you fail from the lab, you will also fail from the course.

In each laboratory lesson;

The students will enter **ZOOM** platform.

The lesson will be started with entrance quiz. The students will download quiz for related experiment from CHE 105 Moodle page. After student uploads of quizzes to Moodle page, theoretical presentation, video experiment, and data sheet presentation will be shown on ZOOM platform. After that, the students will download report sheet for related experiment from CHE 105 Moodle page and follow the steps below.

QUIZ AND REPORT SHEET SUBMISSION STEPS

1- ENTRANCE QUIZ SUBMISSION

Follow the steps given below to submit your entrance quiz.

1- Download **EXP # QUIZ** File to your computer.

2- Write your name, surname, student ID and section information to all papers. Answer each question **WITH HANDWRITING**. **Do not forget to write question number before your answer.**

3- Take a picture of each question number and answer.

4- Send the picture from your mobile phone to your computer by either email or USB cable.

4- Open a blank Word file and insert each answer to Word file.

5- Once you complete **EXP # QUIZ**, save your Word file as PDF. Name the file as 'Student ID_Name_Surname_EXP # Quiz' (for example 19211110001_ALİ_VELİ_EXP_1_Quiz).

6- Go to Moodle Page and upload the file in to related submission title.

Each student will upload 1 EXP # QUIZ file. You have 3 trial rights to submit your quiz. However, these trials are visible to instructors. Make sure you do not change the submitted file.

2- REPORT SHEET SUBMISSION

Follow the steps given below to submit your report sheet.

1- Download **EXP # REPORT SHEET** File to your computer.

2- Write your name, surname, student ID and section information to all papers. Answer each question one by one **WITH HANDWRITING**. **Do not forget to write question number before your answer.**

3- Take a picture of each question number and answer separately.

4- Send the pictures from your mobile phone to your computer by either email or USB cable.

4- Open a blank Word file and insert each answer to Word file separately.

5- Once you complete **EXP # REPORT SHEET**, save your Word file as PDF. Name the file as 'Student ID_Name_Surname_EXP_#_REPORT_SHEET

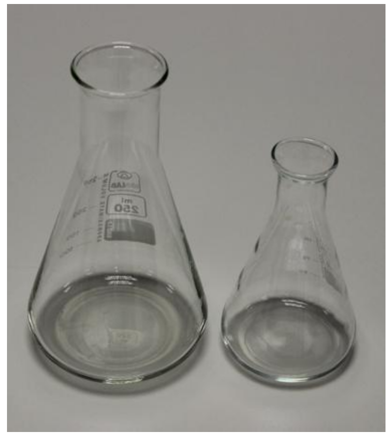
(for example 19211110001_ALİ_VELİ_EXP_1_REPORT_SHEET) .

6- Go to Moodle Page and upload the file in to related submission title.

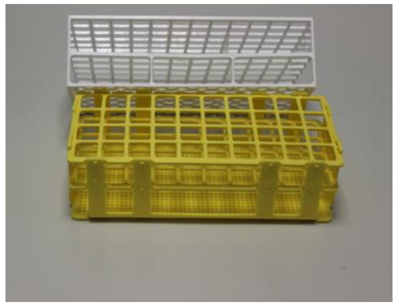
Each student will upload 1 EXP # REPORT SHEET file. You have 3 trial rights to submit your report sheet. However, these trials are visible to instructors. Make sure you do not change the submitted file.

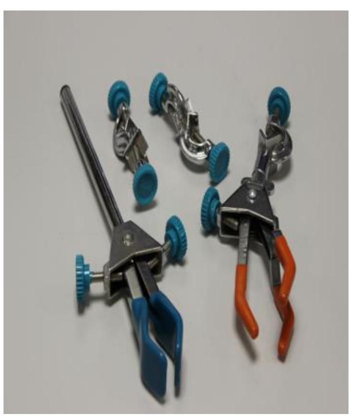
THE ZOOM IDs FOR EACH SECTION WILL BE ANNOUNCED ON CHE 105 MOODLE PAGE LATER. CHECK THE WEB PAGE OF CHE DEPARTMENT AND MOODLE PAGE OF THE CHE 105 COURSE REGULARLY.

LABORATORY EQUIPMENT

Beakers	Erlenmeyer Flask	Graduated Cylinder
		
Pisette	Thermometer	Burette
		
Test Tube	Condenser	Volumetric Flask

Funnel	Test Tube Rack	Test Tube Holder
		Curicible	Weighing Boat	Balance
		


Clamp	Lab Stand	Bunsen Burner

		
Hood	Goggles	Glove

CHE 105
GENERAL CHEMISTRY

Experiment 1

Introduction to Laboratory Techniques

Purpose: To reinforce the understanding of some common laboratory concepts and techniques while gaining knowledge in data treatment by reporting. In the first part of the experiment, potassium permanganate solution (solid $KMnO_4$ dissolved in water) will be separated into its constituents by distillation, and in the second part, determination of the solubility of a pure substance in a given liquid,or, in the case of two liquids, and the miscibility tests will be done. To reinforce the understanding of some common laboratory concepts and techniques while gaining knowledge in data treatment by reporting. In the first part of the experiment, potassium permanganate solution (solid $KMnO_4$ dissolved in water) will be separated into its constituents by distillation, and in the second part, determination of the solubility of a pure substance in a given liquid,or, in the case of two liquids, and the miscibility tests will be done.

Pre-laboratory Work

Before the experiment in the laboratory, you should be able to answer these questions.

1) List five physical properties.
2) What are the differences between physical and chemical changes?
3) Define solubility and discuss the factors affecting solubility.
4) What is density? How do you calculate it?

Theory

Separation of Substances

All material things which have mass and occupy space in universe referred to as **matter**. Every substance has a large number of physical and chemical properties. **Physical properties** are the characteristics of a substance that can be seen without changing the composition of it. Common physical properties include color, smell, taste, solubility, density, electrical conductivity, heat conductivity, melting and boiling points. When a physical change is observed, the substance retains its chemical identity, but loses only its appearance. For example, when ice is melted, only a change of the state occurs, no new substance is formed.

On the other hand, **chemical properties** represent the changes in the composition of a substance when it reacts with other substances or decomposing into new other pure substances. Chemical properties include decomposition by heating, and reactions of the substance with water, oxygen, acids, bases. When chemical changes are observed, new substances are formed that have totally different properties and compositions considering to starting material. For example, when methane, the main component of natural gas, burns by reacting with oxygen in the air, carbon dioxide and water are formed as the new products.

In other words, while physical changes are **reversible**, chemical changes are **irreversible** (not reversible).

Solutions

When a solid is mixed with a liquid and dissolves in that liquid, the resultant mixture formed is called a **solution**. This liquid solution may contain no visible solid particles and it may be colorless or have a characteristic color. Solutions are **homogenous mixtures**. When a solution forms, it can be stated that "The solid dissolves in the liquid" or "The solid is soluble in the liquid". The constituents of a solution are **solute** (minor fraction), and **solvent** (major fraction)

Solubility and Miscibility

Solubility can be defined as the amount of a particular substance that can dissolve in a particular solvent. The maximum amount of a particular substance that can be dissolved in 100 mL of pure water at a particular reference temperature is known as percent solubility. When a solid dissolves in a liquid, it is said to be **soluble** in that liquid. If the solid does not dissolve, then it is **insoluble.**

Miscibility is taken into account when two liquids are mixed. If this mixture is completely uniform in appearance, in this case the liquids are said to be **miscible.** If individual layers are formed when they are poured together, then these two liquids are not miscible at all, i.e. they are **immiscible.**

Density

Density is simply defined as "mass per unit volume". If you wonder how dense a material is, you have to know the mass and volume of it. Then, you can easily find the density of the substance by using this formula: $\rho = m / V$

The unit of the density is g / mL or g / cm^3.

In Part A, water will be separated from potassium permanganate by *distillation*. When the potassium permanganate solution is heated, water vapor will be driven off first, because the boiling point of potassium permanganate is much higher than that of water.

In Part B, The behavior of two substances on a solvent will be tested. For these two chemicals, solubility in water will be examined. For the dissolving one, solubility amount will be found. Then, miscibility of some liquids will be tested.

In Part C, Density of water will be measured in two different ways. Then, the density of an unknown solid will be calculated.

Materials

Potassium permanganate ($KMnO_4$)	Diethyl ether	50 mL beakers
Starch	Ethyl alcohol	Balance
Sodium carbonate (Na_2CO_3)	Bunsen burner	Graduated cylinder
Distilled water	One holed rubber stopper	Ring, clamp
Any solid particle	Boiling chips	

Procedure

Part A: Separation by Distillation	
1. Pour 30 mL potassium permanganate solution (solid $KMnO_4$ dissolved in water) into a 100 mL round bottom flask. Add some boiling chips into the flask to make solution boil calmly.	
2. Set a simple distillation apparatus by inserting the short end of the glass tubing acting as condenser in a one-holed rubber stopper.	
3. Ask your assistant how to use the Bunsen burner. Light it and adjust until you have a small and continous hot flame.	
4. Heat the $KMnO_4$ solution and observe the hot solvent vapors of the solution are cooled and dripped into the test tube. Continue distillation process until about 10 mL of liquid have distilled over. Observe the differences in color between the distillate and the original solution; write these observations on your data sheet.	

Part B: Identifying Substances by Their Properties	
B.1. Solubility in Water	
1. Take clean two test tubes and fill them with 20 ml of water.	2. Take small amount (approximately half of a pea) of sodium carbonate; Na_2CO_3, and starch and place them into test tubes that contain water. Shake the tubes gently and observe whether or not the substances dissolve. Some substances dissolve slowly, in this case set the test tube aside for few minutes and examine again. Are the compounds soluble or insoluble? Record your observations.	
B.2. Miscibility	
1. Take clean two test tubes and fill half of them with water.	2. Now, to the first tube, put some amount of alcohol and to the second one, put diethyl ether. Shake the test tubes gently or mix the contents with stirring rod. Observe what happened. Which one is miscible, record your observations on your data sheet.	

Part C: Density Measurement	
C.1. Density of Water	
1. Now take a clean and dry graduate cylinder and weigh it. Then put 20 mL water in it and weigh again to find the mass of water. Carry out the density calculation and find the density of water.	
C.2. Density of a Solid	
1. Take an irregular shape solid from your assistant and weigh it.	
2. To find volume of the solid, put it into graduated cylinder that contains 20 ml water in the previous part and calculate the volume of the solid according to increase in the water level. Carry out the density calculation to find the density of the solid material.	

DATA SHEET

Introduction to Laboratory Techniques

Student's Name : Date:

Laboratory Section/Group No :

Assistant's Name and Signature:

A. Separation by Distillation:

i. What was the color of the original ($KMnO_4$) solution?

ii. What is the color of the distillate which is collected in the test tube?

iii. Why did we collect water as distillate in test tube? (Hint: Consider the boiling point differences of distinct substances)

B. Identifying Substances by their Properties

	Solubility in water (soluble or insoluble)
Starch	
Na_2CO_3	

	Miscibility (miscible or immiscible)
Water - Alcohol	
Water- Diethyl ether	

C. Density

i. Density of water while you use graduated cylinder:

ii. Density of the irregular shape solid:

CHE 105
GENERAL CHEMISTRY

Experiment 2
The Law of Definite Proportions

Purpose: To understand " the law of definite proportions" concept and to learn how to make gravimetric analysis (analysis by weighing) calculations.

Prelaboratory Work

Before the experiment in the laboratory, you should be able to answer these questions.

1. Define the terms "compound" and "catalyst".

2. How do empirical and molecular formulas differ?

3. Calculate the percent composition of HNO_3? (H: 1 g/mol; N: 14 g/mol; O: 16 g/mol)

4. What is law of definite proportions?

5. How many lithium atoms are present in 0.01456 g of lithium?

6. What is percent oxygen by weight in water molecule?

7. Given that zinc chloride has a formula weight of 136.28 g/mol, what is its formula?

Theory

The law of definite proportions states that a chemical compound always contains exactly the same **proportion** of elements by mass. Law of definite proportions shows a good way to find percent weight or exact weight of a desired element in a compound. It also gives useful information to find empirical or molecular formula for a compound and percent weight of a compound in an unknown mixture.

Example: What is the % O by weight inV_2O_5? (Atomic weights are; V: 50.9 g/mol, O: 16 g/mol)

Solution: First, we must find the total weight of the compound. Then we will divide the desired element's weight by the total weight as in follow:

$$O\% = \frac{5\times(16.0)}{2\times(50.9)+5\times(16.0)}\times 100 = 44.0\%$$

In today's experiment, potassium chlorate ($KCI0_3$) will be decomposed into potassium chloride (KCI) and oxygen (0_2) by heating ($Mn0_2$ will be used as a catalyst to speed up the reaction without being consumed.) :

$$2KClO_3(s) \xrightarrow{\Delta} 2KCl(s) + 3O_2(g)$$

As it is seen from the reaction equation, oxygen gas releasing upon decomposition results with the weight loss of initial compound. In other words, the weight difference gives the weight of oxygen in the compound.

At the end of the experimental part, theoritical and experimental percent oxygen by weight for $KCIO_3$will be calculated and compared. Comparison will give the <u>Percent Error</u> for the experiment.

Percent error is the ratio of the absolute value of the error to the theoritical value and multiplied by 100.

Error: experimental value – theoritical value

% Error: $\frac{|\text{exp}erimental - theoritical|}{theoritical}\times 100$

Example: A chemical compound theoritically contains 39.2 % O by weight. In a laboratory, % O by weight for this compound was found as 36.3 %. Calculate the error and % error of this experiment.

Solution:

Error $= 36.3 - 39.2 = -2.9$

% Error = $\dfrac{|36.3 - 39.2|}{39.2} \times 100 = 7.4\%$

Materials

Manganese (IV) oxide (MnO_2)	Test tube	Bunsen Burner
Potassium chlorate ($KCIO_3$)	Balance	Wooden Tongs
Potassium chloride (KCI)		

Procedure

Part A: Percent Oxygen in Potassium Chlorate	
Drying the Catalyst	
1. Put about a tea-spoon of MnO_2 in a dry test tube. Heat the test tube in order to remove the moisture of the catalyst. Move the test tube continuously on the flame.	
2. After test tube is cooled to room temperature, weigh it (W_1).	

Decomposition Reaction	
1. Add about between 2 - 4 g of $KClO_3$ into the test tube and weigh again (W_2). Calculate the weight of $KClO_3$ (W_3=W_2-W_1).	 
2. Start to heat the test tube in a diagonal position first gently, then more strongly. Heat the entire test tube to redness, and maintain the temperature for <u>fifteen minutes</u>. The mixture will first melt, then effervesce (produce gas) strongly, and finally solidify. **DON'T KEEP OPEN SIDE OF THE TEST TUBE TOWARDS YOUR AND YOUR LAB-MATES FACES! Oxygen release can sputter very hot content as well! Move the test tube continuously on the flame, otherwise the glass may melt.**	
3. Cool the test tube slowly and weigh (W_4).	
4. Heat the test tube and the contents to redness for additional <u>five minutes.</u> Cool and reweigh (W_4).	 
5. Repeat Step 8 until your last weight will be the same with previous one. Your last weighing is W_f. Same weight means; you removed all of the oxygen from your compound. Calculate the weight of oxygen given off, W_{ox}. Calculate experimental percent oxygen by weight in $KClO_3$. Calculate the theoretical percent of oxygen in $KClO_3$. The atomic weights are as follows: O=16.0 g/mol; Cl=35.5 g/mol; K=39.l g/mol. Calculate % Error as explained in theoritical part.	

Part B: Analysis of a $KClO_3$ - KCl Sample	
1. The composition of an unknown $KClO_3$ – KCl will be determined with the same procedure as in Part A. Take your unknown sample from your assistant. Follow the same procedure used in Part A with the unknown mixture instead of pure $KClO_3$. Use the same notations (similar to Part A 1-11). Calculate the percent $KClO_3$ by weight in your unknown sample (see your data sheet).	

Questions

1) How many kilograms of copper sulfide could be formed from the reaction of 2.70 mol of copper with excess sulfur?

2) Given that zinc chloride has a formula weight of 136.28 g/mol, what is its formula?

3) Calculate the percent composition of HNO_3? (H: 1 g/mol; N: 14 g/mol; O: 16 g/mol)

CHE 105
GENERAL CHEMISTRY

Experiment 3
Titration of Acids and Bases

Purpose: To become familiar with the techniques of titration, a volumetric method of analysis; to determine the molarity and pH of an acid solution.

Prelaboratory Work

Before the experiment in the laboratory, you should be able to answer these questions.

1. What is the definition of standardization?
2. What is the definition of titration?
3. What is the definition of molarity?
4. Write the difference between equivalence points and end points.
5. Find the molarity of a solution that contains 3.78 g of $H_2C_2O_4.2H_2O$ in 100 mL of solution?

Theory

According to Arrhenius, **acid** is a chemical substance which gives hydronium ion, H_3O^+, when dissolved in water. Also, Bronsted-Lowry defined that acid acts as a proton donor. On the other hand, Arrhenius defined **base** in a way that it gives hydroxide ion, OH^-, when dissolved in water. According to Bronsted-Lowry, base acts as a proton acceptor.

One of the most common and familiar reactions in chemistry is the reaction of an acid with a base. This reaction is named as ***neutralization*** reaction, and the essential feature of this process in aqueous solution is the combination of hydronium ions with hydroxide ions to form water.

$$H_3O^+_{(aq)} + OH^-_{(aq)} \rightarrow 2H_2O_{(l)}$$

In this experiment, you will perform this reaction to determine accurately the concentration of a sodium hydroxide solution that you have prepared. The process of determining the exact concentration (molarity) of a solution is called ***standardization***. Next you will measure the concentration of the unknown acid solution. For this purpose you are expected to measure the volume of your standard base that is required to exactly neutralize the unknown acid solution. The technique of accurately measuring the volume of a solution required to react with another reagent is termed ***titration***.

During titration, you will use an ***indicator*** solution to understand whether you could neutralize your acid with a base or vice versa. Indicators change colors at different pH values. For example, phenolphthalein changes color from colorless to pink at a pH of about 9; in slightly more acidic solutions it is colorless, whereas, in more alkaline solutions it is pink. The color change is termed the ***end point*** of the titration.

The point at which stoichiometrically equivalent quantities are brought together is known as the ***equivalence point*** of the titration. It should be noted that the equivalence point in a titration is a theoretical point.

Molarity (M) is used to define concentration of a solution more clearly, and it is defined as the number of moles of solute per liter of solution, or the number of millimoles of solute per milliliter of solution:

$$\text{M}=\frac{moles.solute}{volume.of.solution}=\frac{10^{-3}\,mole}{10^{-3}\,liter}=\frac{mmol}{mL} \qquad [1]$$

Ph concept

pH is a concept that is used to measure the acidity of a solution. It is related to concentration of H_3O^+ ion in molarity.

$$HA + H_2O \leftrightarrow H_3O^+_{(aq)} + A^-_{(aq)}$$

The concentration of $[H^+]$ may change over a wide range of values and these values are frequently expressed in terms of exponential numbers. For this reason, a simpler form of representation for $[H^+]$ is provided as follows: **pH = -Iog[H⁺]**

There is another concept named aas **pOH**. It is used to measure the basicity of the solution and related to concentration of OH^- in molarity: **pOH = -log[OH⁻]**

When water is self ionized, hydronium and hydroxide ion formed in equal amounts:

$$H_2O \leftrightarrow H_3O^+_{(aq)} + OH^-_{(aq)}$$

$K_w = [H^+][OH^-]$

$K_w = 1.0\text{x}10^{-14}$ at 25^0C

Therefore;

pH + pOH = 14

Example: What are the pH values for **a)** 0. 1 M HCl and **b)** 0. 1 M NaOH?

Solution:

a) HCI is a strong acid, it dissociates almost completely in aqueous solution. Therefore 0.1 M HCl gives 0.1 M H^+ and 0. 1 M Cl^-.

$$HCl \rightarrow H^+ + Cl^-$$

$[H^+] = 0.1$ M

pH = -Iog(0. 1) = 1.00

b) NaOH is a strong base; it dissociates almost completely in aqueous solution. 0.1 M NaOH gives 0.1 M Na^+ and 0. 1 M OH^-.

$$NaOH \rightarrow Na^+ + OH^-$$

$[OH^-] = 0.1$ M

$[H^+] = Kw/ [OH^-] = 1 \times 10^{-14} /0.1 = 1.0 \times 10^{-13}$ M.

pH = $-\log(10 \times 10^{13}) = 13.00$

or, pH + pOH = 14   1 + pOH = 14 then, pOH = 13

Strong Acid-Base Titrtion

As an example for neutralization reaction between strong acid (e.g. HCl) and a strong base (e.g. NaOH);

$$HCl\ (aq) + NaOH\ (aq) \rightarrow NaCl\ (aq) + H_2O\ (l)$$

As a result, for a monoprotonic acid and base at the end point;

$M_{acid}V_{acid} = M_{base}V_{base}$

In this experiment, we use an acid-base indicator, phenolphthalein to determine the end point in the titration. We choose an indicator such that its color change occurs as closely as possible to the equivalence point.

Materials

Sodium hydroxide (NaOH)	600 mL beaker	Ring stand
Hydrochloric acid (HCl)	250 mL Erlenmeyer flasks	Buret clamp
Phenolphthalein solution	50 mL buret	Balance
Wash bottle	500 mL erlenmeyer flask	

Procedure

Part A: Standardization of Sodium Hydroxide Solution	
1. Fill the buret with the NaOH solution and remove the air from the tip by running out some of the liquid into an empty beaker. Make sure that the lower part of the meniscus is at the zero mark or slightly lower.	2. Take 15.00 mL of standard HCl solution into a clean Erlenmeyer flask and add a few drops of phenolphthalein solution.	
3. Start to add the sodium hydroxide solution slowly to your flasks of HCl solution while gently swirling the contents of the flask. As the sodium hydroxide solution is added, a pink color appears where the drops of the base come in contact with the solution. This coloration disappears with swirling. As the end point is approached, the color disappears more slowly, at which time the sodium hydroxide should be added drop by drop. The end point is reached when the colour of the solution turns from colorless to pink.	
4. Read the buret and record it. Repeat this procedure for two times. From the data you obtain in the three titrations, calculate the molarity of the sodium hydroxide solution to four significant figures.	

Part B: Analysis of an Unknown Acid	
1. Obtain 15 mL of the unknown solutions. Add a few drops of phenolphthalein solution and titrate against the standard NaOH solution as in Part A.	
Questions

1. Write the balanced chemical equation for the reaction of HCl with NaOH.

2. A solution of malonic acid, $H_2C_3H_2O_4$, was standardized by titration with 0.100 M NaOH solution. If 21.82 mL of the NaOH solution were required to neutralize completely 12.12 mL of the malonic acid solution, what is the molarity of the malonic acid solution?

3. Sodium carbonate is a reagent that may be used to standardize acids in the same way. In such standardization it was found that a 0.432-g sample of sodium carbonate required 22.3 mL of a sulfuric acid solution to reach the end point for the reaction.

$Na_2CO_3(aq) + H_2SO_4(aq) \rightarrow H_2O(l) + CO_2(g) + Na_2SO_4(aq)$

What is the molarity of the H_2SO_4?

4. A solution contains 0.252 g of oxalic acid, $H_2C_2O_4.2H_2O$, in 500 mL. What is the molarity of this solution?

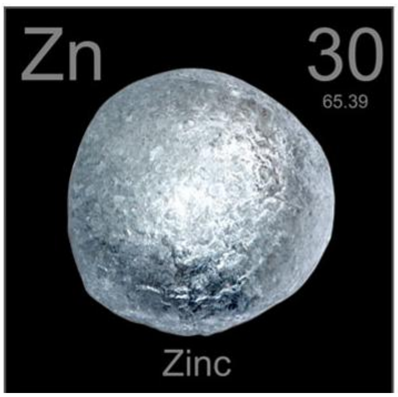
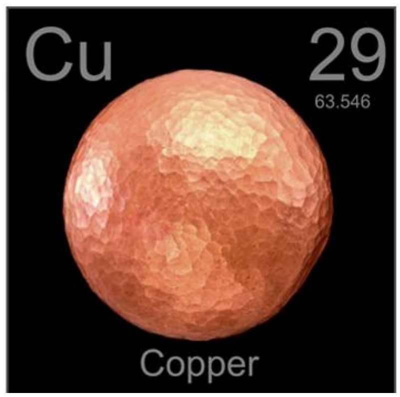
CHE 105

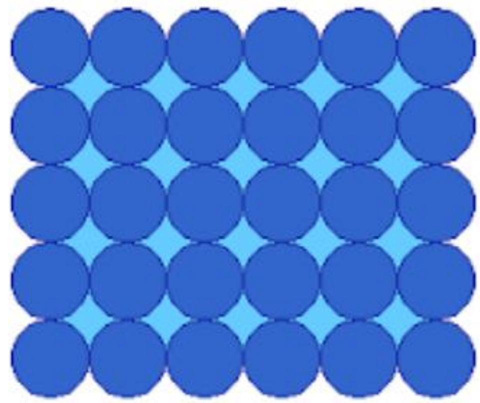
GENERAL CHEMISTRY

Experiment 4

Determination of The Atomic Weight of a Metal







Purpose: To determine atomic weight of a metal by measuring the volume of the hydrogen gas liberated from the oxidation of a metal with an acid reaction.

MATERIALS:

A piece of metal	Beaker	Methyl orange
Cotton	Burette	Hydrochloric acid (HCl)

THEORY:

A metal, which is a good reducing agent, will react with hydrochloric acid, liberating hydrogen gas and forming a salt.

M (solid) + nH^+ (aqueous) --- > M^{n+} (aqueous) + n/2 H_2 (gas)

In this experiment, a weighted sample of metal will be completely dissolved in HCl solution, and the volume of hydrogen liberated will be determined from the volume of water that it displaces. From this data the atomic weight of the metal will be calculated. This calculated value is the experimental value of the atomic weight of the metal.

After the determination of the atomic weight of the metal, your assistant will tell you the name and the atomic weight of the metal (theoretical value). Now, you can calculate percentage error of atomic weight calculation. The valence of the metal is taken as n+ for the reaction given above.

A mole is defined as the amount of substance that contains the same number of chemical units as the number of atoms in exactly 12.0000 g of ${}^{12}_{6}C$

1 mole ${}^{12}_{6}C$ atoms = 12.0000 g ${}^{12}_{6}C$

A mole of atoms, therefore, consists of Avogadro's number of atoms and has a mass in grams numerically equal to the atomic weight of the element, shortly.

Number of moles of an atom $= \frac{\text{weight}}{\text{Atomic Weight}}$

Number of moles of a molecule $= \frac{\text{weight}}{\text{Molecular Weight}}$

Before doing this experiment, it will be necessary for the student to review his knowledge about the ideal gas equation.

Ideal Gas Equation:

The behavior of an ideal gas is expressed by the well-known equation given below.

PV = nRT   Ideal Gas Equation

In the equation the units are under STP (1 atm and 0 °C, 273 K) 1 mole of ideal gas occupies 22.4 L volume. So;

$$R = \frac{(1\ atm) \times (22.4\ L)}{(1\ mol) \times (273\ K)} = 0.00823\ {}^{L \times atm}/_{mol \times K}$$

EXAMPLE 1:

Standard conditions are defined as 0^oC and 1 atm for temperature and pressure, respectively. Using ideal gas equation, calculate the volume that is occupied by one mole of an ideal gas under the standard conditions (STP).

SOLUTION:

$T = 0^oC$

$T = 0^oC + 273.15 = 273.15$ K

PV = nRT V = nRT/P

$V= (1 \text{ mole})*(0.082 \text{ L.atm.mole}^{-1}K^{-1})*(273 \text{ K}) / 1 \text{ atm}$

V=22.4 L/mole

EXAMPLE 2:

In a reaction, 334 mL of H_2 gas is liberated at a pressure of 674 mm Hg and a temperature of 17^oC. Calculate the number of moles of H_2 gas liberated.

SOLUTION:

760 mm Hg = 1 atm

P = (674 mm Hg)*(1 atm /760mm Hg) = 0.887 atm

$T = 17^oC + 273.15 = 290.15$ K

V = 0.334 L

$R = 0.082 \text{ L.atm.mole}^{-1}K^{-1}$

$$n = \frac{PV}{RT} = \frac{0.887 \times 0.334}{0.082 \times 290.15} = 0.012 \text{ moles of } H_2$$

EXAMPLE 3:

0.26 g of an unknown metal is liberating 0.004 moles of H_2 gas. If the valence of this metal is 2+, find the atomic weight of this metal. Find the name of this metal using the periodic table.

$X(\text{solid}) + nH^+ (\text{aqueous}) \text{ --- > } X^{n+} (\text{aqueous}) + n/2\ H_2 (\text{gas})$

SOLUTION:

According to the stoichiometry of the reaction;

Number of moles of metal equals to the number of moles of the metal

Number of moles= $\frac{\text{weight}}{\text{Atomic Weight}}$ $\longrightarrow$ At. Wt. = $\frac{\text{weight}}{\text{number of moles}} = \frac{0.26}{0.004}$ = 65.0 g/mole

Closest value to this experimental atomic weight value is 65.39, thus the metal is predicted to be Zinc.

Table 1: Conversion of pressure units

Units	Pa	psi	atm	bar	torr
Pa	$1 N/m^2$	1.45×10^{-4}	9.869×10^{-6}	10^{-5}	7.5×10^{-3}
psi	6.894×10^3	$1 lb/in^2$	6.8×10^{-2}	6.894×10^{-2}	51.714
atm	1.01325×10^5	14.695	P_0	1.01325	760
bar	10^5	14.5	0.9869	10^6 $dyne/cm^2$	750
torr	133.322	1.93×10^{-2}	1.315×10^{-3}	1.333×10^{-3}	1 mmHg

Dalton's Law of Partial Pressure

Dalton's Law (also called Dalton's Law of Partial Pressures) states that the total pressure exerted by the mixture of non-reactive gases is equal to the sum of the partial pressures of individual gases. Mathematically, this can be stated as follows:

$$P_{total} = P_1 + P_2 + P_3 + \cdots + P_n$$

where P_1, P_2 and P_n represent the partial pressures of each compound. It is assumed that the gases do not react with each other.

Collecting Gases Over Water

The amount of gas present can be determined by collecting a gas over water and applying Dalton's Law.

EXAMPLE 4:

O_2 gas is collected in a pneumatic trough with a volume of 0.155 L until the height of the water inside the trough is equal to the height of the water outside the trough. The atmospheric pressure is 754 torr, and the temperature is 295 K. How many moles of oxygen are present in the trough? (At 295 K, the vapor pressure of water is 19.8 torr.)

SOLUTION:

The total pressure in the tube can be written using Dalton's Law of Partial Pressures:

$$P_{total} = P_{H_2O} + P_{O_2}$$

Rearranging this in terms of P_{O_2}, we have:

$$P_{O_2} = P_{total} - P_{H_2O}$$

Because the height of the water inside the tube is equal to the pressure of the water outside the tube, the total pressure inside and outside the tube must be equal to the atmospheric pressure. With substitution, we have:

$$P_{O_2}=P_{total}-P_{H_2O}=754-19.8=734\text{ torr}=0.966\text{ atm}$$

Next, we apply the Ideal Gas Law:

$$n=\frac{P\times V}{R\times T}=\frac{(0.966\text{ atm})\times(0.155\text{L})}{(0.082\ {}^{\text{L}\times\text{atm}}/_{\text{mol}\times\text{K}})\times(295\text{K})}=0.00619\text{ mol } O_2$$

Table 2: Partial pressure values of water at different temperature values

T(°C)	P(torr)
17	14.5
18	15.5
19	16.5
20	17.5
21	18.7
22	19.8

T(°C)	P(torr)
23	21.1
24	22.4
25	23.8
26	25.2
27	26.7
28	28.4

PROCEDURE:	
1. Mix 20 mL of 3M HCl and 1 drop of methyl orange and pour it into a burette.	
2. Add distilled water up to 5 mL scale of same burette.	

3. Weigh out about 1 cm length of your metal. Record this weight.	
4. Take the sample and place it in a small bag made from a piece of cotton. (Wrap around the metal by a piece of cotton.)	
5. Tie this metal in cotton with a piece of thread and hang it a few centimeters above from the top of the liquid in the burette, providing that it does not come into contact with the acid solution. You may drop it into the solution as well.	

6. Make sure your set-up look like in the figure.	7. Put some water in the beaker and set up the apparatus as shown in the figure, read and record the first height of pink acidic solution (V_1).	
8. Make sure the cotton is stacked at the end of burette. When the system is shown to be airtight, wait until the acid solution comes in contact with the metal. You will see the hydrogen gas is being produced as bubbles near the metal, and some water will pour into the beaker.	
9. After the metal has completely dissolved, read the volume of the water in the burette and record it (V_2). The displaced amount of water in mL will be taken as the amount of hydrogen gas liberated. Record the room temperature. Record the atmospheric pressure, P_{atm} and the vapor pressure of water, P_{H_2O} at this temperature.	

10. Calculate the partial pressure of H_2 gas, P_{H_2} , in the flask; express it in the units of atm.

11. Calculate the number of moles of H_2.

12. What is the number of moles of metal?

13. Calculate the atomic weight of metal.

14. Ask your **assistant the name of the metal.**

15. Ask your assistant the exact atomic weight of the metal.

16. Calculate the percent error for the experimental atomic weight of the metal.

GENERAL CHEMISTRY

Experiment 5

Stoichiometry: The Reaction of Iron with Copper(II) Sulfate

Purpose: To enhance the understanding of stoichiometry, a reaction between iron and copper (II) sulfate ($CuSO_4$) solution will be conducted. This will help you to differentiate limiting and excess reactant in a chemical reaction. Finally the theoretical and percent yield of this reaction will be calculated.

Theory

Stoichiometry is the measurement of quantitative relationships in chemical formulas and equations.

Mostly in chemical reaction two or more reactants (reagents) are placed. The reagent that is totally consumed before other reactants at that time reaction stops defined as **limiting reagent**. Limiting reagent is the reactant which is totally consumed before other reactants. The limiting reactant limits the amount of product that can be formed since the consumption of the reactant stops the reaction.The reactant that is remained once the limiting reagent is consumed is called as **excess reagent**.

Example : How many moles of Ag are in 1.75 mol of Ag_2CrO_4 ?

There are 2 moles of Ag atoms for each Ag_2CrO_4 formula unit

Therefore,

1.75 mol Ag_2CrO_4 x 2 = 3.5 mol Ag

Example: Sodium carbonate**,** Na_2CO_3, reacts with calcium chloride, $CaCl_2$, to form calcium carbonate, $CaCO_3$ and sodium chloride, NaCl . In an experiment 53 grams of Na_2CO_3 and 44.4 grams of $CaCl_2$ were mixed and 23.6 gr $CaCO_3$ was obtained. Which is the limiting reactant? What is the percent yield of $CaCO_3$?

(Molecular weight of Na_2CO_3 = 106 g/mole, $CaCl_2$ =111 g/mole, $CaCO_3$ = 100 g/mole, NaCl=58.5 g/mole)

$$Na_2CO_3(aq) + CaCl_2(aq) \rightarrow CaCO_3(s) + 2NaCl(aq)$$

Mole of Na_2CO_3 : 53/ 106 = 0.3 moles of Na_2CO_3 are present.

Mole of $CaCl_2$: 44.4/ 111 = 0.4 moles of $CaCl_2$ are present.

1 mole of Na_2CO_3 reacts with 1 mole of $CaCl_2$ according to the above equation.

$$\frac{1 \text{ mole } Na_2CO_3}{0.3 \text{ mole } Na_2CO_3} = \frac{1 \text{ mole } CaCl_2}{x}$$ x = 0.3 moles of $CaCl_2$ are needed.

0.3 moles of $CaCl_2$ are needed and 0.4 moles of $CaCl_2$ are present. Therefore, $CaCl_2$ is excess reagent and Na_2CO_3 is limitng reactant.

Since Na_2CO_3 is limiting reactant it limits the amount of the product, $CaCO_3$, that will be formed.

$$\frac{1 \text{ mole } Na_2CO_3}{0.3 \text{ mole } Na_2CO_3} = \frac{1 \text{ mole } CaCO_3}{x}$$ x = 0.3 moles of $CaCO_3$ will be formed

0.3* 100= 30 gr of $CaCO_3$ will be formed. This amount is theoretical yield. Since the actual yield is the amount of product given, the percent yield will be calculated by the formula given below;

Percent yield = $\frac{\text{actual yield}}{\text{theoretical yield}} \times 100$

Then, percent yield for $CaCO_3$ is;

(23.6/30)*100 =78.7%

In this experiment stoichiometric principles will be used to obtain the appropriate equation between the reaction of iron metal and copper(II) sulfate solution. Whent the reaction starts, the formation of metallic copper, which is precipitating during reaction as a finely divided reddish-orange powder will be observed. This reaction is one of the example of single substitution reaction in which one element "displaces" with another element in a compound The element which has ability of displacing other element from a compound is said to be "more active" than the displaced one. In this experiment, iron is more active than copper.

Two distinct forms of iron are present, namely Ferrous, $Fe^{2+}$and Ferric, Fe^{3+}. Stoichiometric principles will be used to determine which reaction is more dominant compared to other by examining the reaction between iron and copper (II) sulfate solution. If Fe^{2+} is formed, then **equation (1)** is dominant, but **equation (2)** will be selected if Fe^{3+} is formed. This can be determined by taking the mole ratio of copper to iron. If the moles of copper is equal to the moles of iron, then equation (1) has taken place. If you obtain 1.5 moles of copper per mole of iron, in this case equation (2) should be selected Find out which equation is corresponding to the results of the experiment you have done.

Equation (1) $\mathrm{Fe_{(s)} + CuSO_{4\,(aq)} \rightarrow FeSO_{4\,(aq)} + Cu_{(s)}}$, other representation is

$$\mathrm{Fe_{(s)} + Cu^{2+}{}_{(aq)} \rightarrow Fe^{2+}{}_{(aq)} + Cu_{(s)}}$$

Equation (2) $\mathrm{2\ Fe_{(s)} + 3\ CuSO_{4\,(aq)} \rightarrow Fe_2(SO_4)_{3\,(aq)} + 3\ Cu_{(s)}}$,

other representation is

$$\mathrm{2\ Fe_{(s)} + 3\ Cu^{2+}{}_{(aq)} \rightarrow 2\ Fe^{3+}{}_{(aq)} + 3\ Cu_{(s)}}$$

To the known amount of iron, excess of copper (II) sulfate solution will be added. The purpose of using excess solution is owing to provide the complete reaction of iron. The metallic copper produced will be weighed after washing and drying processes and these weighings will be used to calculate the moles of iron used and the moles of copper formed at the end of the raection.

Materials

Fe powder	Acetone	Glass stick
Cupper (II) Sulfate ($CuSO_4$)	Beaker	Bunsen burner

Procedure

The Reaction of Iron with Copper(II) Sulfate	
1. Weigh a dry and clean 100 or 250 mL beaker and record the weight of it onto your data sheet. then, accurately weigh 1.00 gram of iron powder into this beaker. Do not exceed 1.01 grams.	2. Measure 30 mL of 1.0 M $CuSO_4$ solution by using a graduated cylinder. Pour this solution into another beaker, and heat gently to almost boiling.	
3. Slowly add hot $CuSO_4$ solution to the beaker that contains the iron powder. Stir the mixture a few times until completeness of the reaction. You should see copper forming. When the reaction has finished, allow the copper product to cool.	
4. Then carefully decant the liquid from the copper into the waste container. Be careful not to lose any copper.	
5. Add about 10 mL of distilled water to the solid copper and swirl to wash any remaining ions from the copper. Decant the wash water from the copper and add 10 more mL of distilled water, swirl and decant again. Wash copper particles finally with several mL of acetone (**CAUTION**-Acetone is very flammable). Swirl and allow to stand a few minutes. Decant off the acetone.	
6. The acetone readily dissolves the water and helps the removal of it from the medium. Swirl the beaker gently on low heat flame. Copper product should be spread in a single layer on the bottom of the beaker. Grinding of aggregates with a spatula makes the copper easy to dry. Be sure not to remove any copper from the beaker.	7. After drying, allow copper to cool and weigh the beaker plus copper to calculate the mass of copper formed. Record the mass on your data sheet. Finally, calculate the moles of iron used and the moles of copper formed to determine which reaction of iron is taking place, reaction (1) or reaction (2).

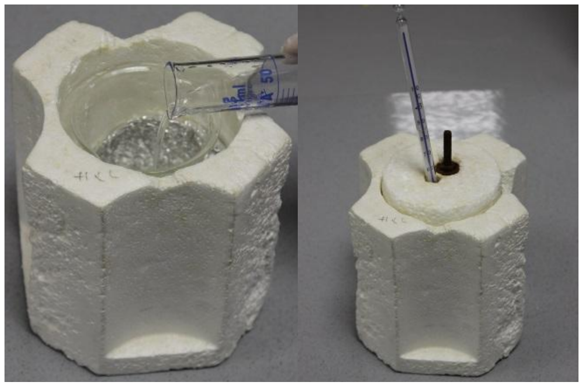
GENERAL CHEMISTRY

Experiment 6

Heat of Neutralization



Purpose: To calculate enthalpy change of a reaction by using calorimeter and understand the difference between endothermic and exothermic reactions

Prelaboratory Work

Before the experiment in the laboratory, you should be able to answer these questions.

1. Calculate the volume of solution of 1.50 M HNO_3 required in part (A) of the procedure.

2. Calculate the mass of NH_4NO_3 required in part (B) of the procedure. Show your reasoning.

3. Explain in stepwise fashion (number the steps) how you will determine the ΔH of formation of NH_4NO_3 from your data and information given in the experiment. Use actual numbers whenever possible.

4. How many joules are required to change the temperature of 80.0 g of water from 23.3 $^{\circ}$C to 38.8 $^{\circ}$C?

Theory

In chemical reactions, energy change is observed. This energy change is usually in the form of heat and at constant pressure it is defined as **heat of reaction** or **enthalpy change (ΔH).** To form 1 mole of compound from its constituent elements, necessary amount of enthalpy change occurs and this change is defined as **enthalpy of formation**. If heat is released during the reaction, ΔH is shown with negative sign and the reaction is called **exothermic reaction.** If heat is absorbed during the reaction, ΔH is shown with positive sign and the reaction is called **endothermic reaction.**

Direct measurement of enthalpies of formation is difficult experimentally, so indirect methods involving enthalpies of reaction are used. Hess's Law states that the change in a thermodynamic property such as enthalpy depends on the initial and final states and is independent of path followed. An example for Hess's Law is given below.

$\frac{1}{2} N_2(g) + 3/2\ H_2 \rightarrow NH_3(g)$ $\quad \Delta H_{formation}\ (NH_3(g)) = \Delta H_1$

$NH_3(g) \rightarrow NH_3(aq)$ $\quad \Delta H_{dissolving} = \Delta H_2$

Assume that ΔH_1 and ΔH_2 are known. If first and second reactions are added, net reaction becomes;

$\frac{1}{2} N_2(g) + 3/2\ H_2 \rightarrow NH_3(aq)$ $\quad \Delta H_{formation}\ (NH_3(aq)) = \Delta H_1 + \Delta H_2$

which is also formation reaction of $NH_3(aq)$.

Given that ΔH_1 = - 45.8 kJ/mol and ΔH_2 = - 35.4 kJ/mol, we can calculate the ΔH formation of $NH_3(aq)$ as - 81.2 kJ/mol.

The heat is measured experimentally by allowing the reaction to take place in a thermally insulated vessel called as **calorimeter**. If the calorimeter is perfectly insulated, no heat change occurs between system and surrounding and the system is defined as adiabatic (Q=0). Consequently, at constant pressure, ΔH_{system} is also equal to zero. The formulation of enthalpy change of the system, ΔH_{system}, is shown as in Equation (1).

$$\Delta H_{system} = \Delta T\ (\text{heat capacity of calorimeter + heat capacity of contents}) \qquad (1)$$

For endothermic reaction in adiabatic system, Equation (1) can be written as below.

$\Delta H_{system} = n\Delta H_{reaction} + C_p\Delta T$

$0 = n\Delta H_{reaction} + C_p\Delta T$

$n\Delta H_{reaction} = - C_p\Delta T$

In a similar manner, for exothermic reaction in an adiabatic system, Equation (1) can be simplified as:

$\Delta H_{system} = -n\Delta H_{reaction} + C_p\Delta T$

$0 = -n\Delta H_{reaction} + C_p\Delta T$

$n\Delta H_{reaction} = C_p\Delta T$

In this experiment, you will determine the heat of formation of various ammonium salts $NH_4X(s)$ where X is Cl, NO_3 or SO_4 by combining measurements of the heat for the neutralization reaction;

$NH_3(aq) + HX(s) \rightarrow NH_4X(aq)$ $\quad \Delta H_{neut}$

And the heat of the dissolution reaction;

$NH_4X(s) + H_2O \longrightarrow NH_4X(aq) \qquad \Delta H_{diss}$

with known heats of formation of $NH_3(aq)$ and $HX(aq)$.

Materials

Nitric acid (HNO_3)	250 mL beaker	Graduated cylinder
Ammonia (NH_3)	Thermometers	
Ammonium nitrate (NH_4NO_3)	Styrofoam cups	

Procedure

PART A: Heat of Neutralization	
1. Obtain a sytrofoam cup. In the first cup, place 50 mL of 1.5 M NH_3.	
2. Place a thermometer in the cup containing the NH_3 and record temperature at 30 seconds intervals.	3. Add the acid solution to the NH_3 and swirl to mix. Continue taking temperature data at 30 seconds intervals while swirling the solution occasionally.	
PART B: Dissolving	
1. Place a volume of distilled water equal to the final volume of solution from part (A) in a Styrofoam cup and record temperature data at 30 seconds intervals.	 2. Weigh out that mass of NH_4NO_3 salt into a clean, dry beaker.	
3. Immediately, add the weighed amount of salt, swirl to dissolve (use stirring rod if necessary), and continue taking temperature data at 30 seconds intervals.	

Calculations

1. Plot temperature versus time graph using your data and determine ΔH_{neut} for (a) and ΔH_{diss} for (b).

2. Take ΔH_f of 1.5 M NH_3 as -81.2 kJ/mol and ΔH_f of 1.5 M HCl as -165.1 kJ/mol, calculate the ΔH_f of NH_4Cl(s).

3. Do the same calculations for NH_4NO_3(s) using -206.0 kJ/mol for the ΔH_f of 1.5 M HNO_3.

4. Calculate ΔH_f of $(NH_4)_2SO_4$ using -884.2 kJ/mol for the ΔH_f of 1.5 M H_2SO_4. [Note that all ΔH_f are per mol (not per 1.5 mol)]
